Symptomatic neuroma
Symptomatic neuroma may develop after a nerve dissection following any trauma to a peripheral nerve, whether accidental or planned (i.e., surgery). Neuroma-induced neuropathic pain and morbidity seriously affect the patient’s daily life and socioeconomic functioning1. The incidence of symptomatic neuromas after peripheral nerve injury is estimated to be 3-5%, however certain surgeries (e.g., autograft procedures, amputations) may have up to a 30% incidence rate2.

There are several surgical procedures possible to treat symptomatic end-neuromas, but none are considered gold standard for both treatment and prevention. The most common procedure is surgical removal of the neuroma and surrounding scar tissue, and placing the proximal stump into an area subjected to minimal mechanical stimulation.

Covering the nerve stump
Different ways of pain treatment are available, however with an average of 2.8 re-operations3 and the surgeries have a failure rate of 10% or more4.

Covering the nerve stump with a cap of autologous material prevents both neurora development and regeneration4, but has its limitations.

- Suitable veins need to be available and sacrificed and the stability of the treatment depends upon consistent venous integrity (i.e., no vein collapse).
- Muscle capping is often performed as this tissue is easily available, however the recurrence of very painful sensory neuroma has been reported5. Replacing the refreshed nerve end into bone is a technically demanding option.
- The nerve stump must be properly placed into a drilled hole, with no kinking at the hole entrance, and requires the nerve to be fixed to prevent dislocation.
- Use of vascularized flaps is technically very demanding and only considered in specific cases6. Research on better fixation techniques and covering the nerve stump with synthetic material bypassing possible biocompatibility issues of animal derived materials led to the idea to develop NEUROCAP®,

NEUROCAP®

NEUROCAP® Management Of Neuroma
NEUROCAP® is intended to protect a peripheral nerve-end and to separate the nerve from surrounding environment to reduce the development of a symptomatic end-neuroma.

NEUROCAP® is a tubular device with one open end and one closed end. Dislocation of the nerve stump is prevented by suturing the nerve end into the cap. A hole at the sealed end of the tube allows easy fixation of the nerve stump with a suture to the surrounding tissue. This allows an effective capping technique without the necessity of drilling a hole into bones, or sacrificing other tissue.

The application of NEUROCAP® and the available device dimensions are illustrated in figure 1 and table 1.

STOP Neuroma Trial
This safety and performance study underlines the effectiveness of Neurocap by demonstrating significant pain reduction, improvement of quality of life and reduction in pain medication use (12 Month data).

PROTECT NEURO Trial
This ongoing study, regarding the long term performance of Neurocap, demonstrates significant pain reduction and reduction in pain medication use, as well as significant improvement of quality of life at 12- and 24-months follow-up (final 24-months data are being collected).

NEUROCAP® is available in 1 unit per box. It is packed in a plastic tray and a Tyvek pouch and subsequently placed in an aluminum pouch.

NEUROCAP® is transparent, indicated for single-use and should be stored in a dark, dry place between -18 °C (0 F) and 8 °C (46 F). The shelf life is 24 months.

NEUROCAP® is FDA cleared under number K152684, and CE-marked as a bioresorbable device for peripheral nerve injury treatment and management.
